**Presentation Title: Thermodynamics and Never-Ending Search for the Truth: Properties, Uncertainties, and Models**

#### Biography

Dr. Michael Frenkel is the director of the TRC and co-developer of the innovative software ThermoData Engine (TDE). He is the 2014 recipient of the Rossini Lectureship Award from the International Association of Chemical Thermodynamics (IACT).

#### Abstract

Most of the reliable and currently-used prediction methods for thermophysical and thermochemical properties (with the exception of *ab initio*) have been developed on the basis of experimental data reported in the open literature. It is, therefore, well understood that discrepancies and errors in the experimental data set used can cause significant problems in the development of robust prediction models for thermodynamic properties (“garbage in — garbage out” computational problem). However, enormous growth in the amount of experimental information reported in the last 20 years in the public domain for thermodynamic properties, while obviously being welcomed as part of the overall scientific discovery process, represents new challenges for property modeling.

Indeed, according to statistics accumulated at the Thermodynamics Research Center (TRC) of the U. S. National Institute of Standards and Technology (NIST), the total number of the experimental data points for thermophysical and thermochemical properties published by five major journals in the field is currently growing by more than a factor of 2 every 10 years. In many instances the traditional peer-review process fails to adequately address these challenges, as it is physically impossible to independently assess the high volume of presented experimental information within the limited time available for a review. There are numerous examples of the truly devastating impact of erroneous experimental data set selection on the development

of prediction models.

Another principal problem commonly associated with reported experimental data is either absence or inconsistent representation of uncertainties that are used in development of advanced prediction models.

The systems and software tools designed for global validation of experimental data in the field of thermodynamics on the basis of Global Information System in Thermodynamics developed at NIST TRC, will be discussed. A variety of experimental data-driven technologies for thermophysical property prediction including those based on QSPR, UNIFAC, and Monte Carlo simulation method will be illustrated. QSPR-based and UNIFAC-based prediction methods developed at NIST TRC will be discussed with the emphasis on the importance of the use of the combined expanded uncertainties of the experimental data selected and performance of the phenomenological data quality tests to obtain high fidelity predictive models.

### **Presentation Title: Thermophysical Properties of Liquid Metals at High Temperatures -Experimental Techniques**

#### **Biography**

Prof. Gernot Pottlacher is a professor at the Institute for Experimental Physics at TUG. His main field of activity are investigations of thermophysical properties of liquid metals and alloys with various techniques such as subsecond pulse heating, DSC (Differential Scanning Calorimetry), and four point probes. His physical hobby is public experimental demonstrations-shows. Up to now he published more than 100 scientific papers and contributed about 180 articles to scientific conferences.

#### **Abstract**

High temperature experimentation with solid and especially liquid specimens faces numerous difficulties. Traditional static steady state techniques for the measurement of thermophysical properties are generally limited to temperatures of about 2300 K. This limitation is a result of chemical interaction of the specimens with the containers, the loss of mechanical strength, problems with heat transfer, evaporation and electrical insulation while the sample and its environment are kept for times up to hours at high temperatures.

Containerless investigation methods have been developed to avoid these difficulties and to permit the extension of the measurements to higher temperatures. The methods used by our workgroup are on the one hand an electromagnetic levitation technique and on the other hand ohmic pulse heating, both can be called containerless techniques.

Pulse heating delivers thermophysical properties of electrically conducting materials far into the liquid phase. The measurements allow the calculation of specific heat capacity and the temperature dependencies of electrical resistivity, enthalpy and density of the samples in the solid and liquid phase. Further measurements of normal spectral emissivity at 684.5 nm are performed to increase the accuracy of the pyrometric

temperature measurements. Thermal conductivity and thermal diffusivity as a function of temperature are estimated from resistivity data using the Wiedemann-Franz-law.

Electromagnetic levitation, as the second experimental approach used, delivers data for surface tension (this quantity is not available by means of pulse heating technique) and for density of liquid metals under investigation as a function of temperature.

Properties of matter at high temperatures are useful for high-temperature technologies such as aerospace, nuclear energy and the establishment of temperature reference points, including applications which are subjected to high temperature - high pressure conditions, as well as input data for modeling, which got very popular recently in steel working industry to simulate casting and welding processes and in jewellery industry to reduce reject due to defects.

Work partially funded by the Austrian Science Fund (FWF) Project P 23838-N20.

## Abstract

Various calorimeters utilizing the Peltier and Seebeck effects of metallic junctions are developed [1]. The Peltier tip calorimeter, for example, employs a Peltier tip which is a single thermocouple junction functioning as a heater and sensor simultaneously. The Peltier tip calorimeter can measure thermophysical properties of not only solids but also of fluids.

When a Peltier tip is used to measure gas pressures, it is termed the Peltier vacuum gauge (PVG); the PVG measures gas pressure by utilizing both Joule heating along the wire and the Peltier effect at the junction. The complementary nature of the Peltier effect and Joule heating allows the PVG to possess an excellent sensitivity over a wide range of pressure from  $10^{-4}$  Torr to atmospheric pressure. Miniaturization of vacuum gauges is achieved via MEMS technology and the MEMS calorimetric sensors offer higher sensitivity, faster response, and better stability. It is noted that a natural heat convection pattern from heated resistive wires located in a cell filled with gases could be used as a marker of the reference frame and thus a temperature sensor could detect acceleration. Miniaturization of the gas convection acceleration sensor via MEMS technology was attempted to manufacture commercial products.

Dynamic calorimeters, Peltier one or otherwise, may also be applied to condensed systems to study relaxation phenomena. Consider water. If one measures the dielectric constant as a function of frequency, it takes a large value 80 at low frequencies and a low value 1.7 at optical frequencies. A transition from the high to low value occurs at 10 GHz, and this frequency marks a characteristic time scale of the system. This behavior observed in water is a typical example of electrical relaxation, and measurements of the relaxation provide an important probe to the dynamics of the system. Relaxation phenomena are ubiquitous in matter as observed in many liquids and glasses, and even in crystals. Here we wish to discuss about calorimetric investigations of the relaxation phenomena in solids and also a possibility of magnetic control of electrical relaxations.

## Venue

Jeju-do is the biggest island in Korea, situated southwest of the Korean peninsula and in the north of the Southern Sea. It embraces 62 isles and has a total area of 1,825 sq. km. It is situated at 126 degrees and 08 minutes ~ 126 degrees and 58 minutes longitude east and 36 degrees 06 minutes ~ 33 degrees 00 minutes latitude north. Jeju-Island is 452 km from Seoul and 301km from Busan. The island is located 989 km from Osaka, 1580 km from Tokyo, 499 km from Shanghai, China, and 1,030km-distance from Hong Kong.

The Jeju Island is famous for 3 things: roaring winds, magnificent rocks, and woman divers for fishing. As one of the host cities of the 2002 Korea/Japan FIFA World Cup, Jeju's Seogwipo City has a fame of the most enchanting environment in Korea. Jeju is a focal point of international affairs and offers many kinds of recreation together with breathtaking vistas, a temperate climate and a unique traditional culture. Located in the center of this volcanically formed island is Mt. Halla (a dormant volcano), which is filled with over 1,800 species of wild plants, wild deers, and an ecosystem, that will surely amaze all visitors.

Jeju also offers unbelievably breathtaking views from coast to coast, ranging from waterfalls at Haean Jidae to naturally sculpted cliffs at Jusang Jeolli. Tourists can enjoy each season in Jeju with a particular splash of color; brilliant yellow-colored flowers in spring that spread across the landscape, the golden beaches and sea vistas in summer, the Eulalia's light brown wispy reeds flowing in autumn winds, and the lovely snow flowers of Mt. Halla in winter are all must-sees of Jeju.

Scopus, the largest abstract and citation database of peer-reviewed literature, features smart tools to track, analyze and visualize research. Scopus delivers the most comprehensive overview of the world's research output in the fields of science, technology, medicine, social sciences and Arts & Humanities. As research becomes increasingly global, interdisciplinary and collaborative, you need to make sure that crucial research from around the world is not missed.

### Updated daily, Scopus includes:

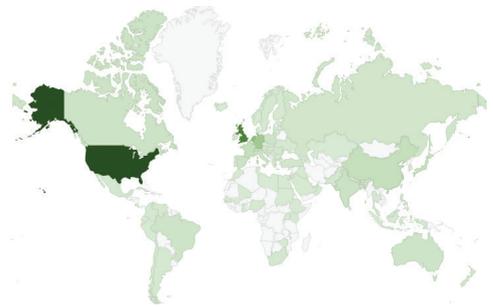

- 21,000 titles from more than 5,000 international publishers
  - 20,000 peer-reviewed journals (including 2,600 open access journals)
  - 390 trade publications
  - 370 book series
- 5.5 million conference papers
- "Articles-in-Press" from more than 3,850 journals and publishers such as Cambridge University Press, Elsevier, Springer, Wiley-Blackwell, Nature Publishing Group and the Institute of Electrical and Electronics Engineers

### Scopus' 50 million records consist of:

- 29 million records, including references, going back to 1995 (84% include abstracts)
- 21 million pre-1996 records going back as far as 1823

Scopus also cross-searches 25.2 million patents from five patent offices (US Patent & Trademark Office, European Patent Office, Japan Patent Office, World Intellectual Property Organization and the UK Intellectual Property Office).
